

## Quantitative Stratigraphic Correlation – A Case Study from Two Borehole Sections of Barakar Formation, Talchir Coalfield, Orissa

R. N. HOTA

Department of Geology, Ravenshaw College, Cuttack-753003, Orissa

**Abstract:** Quantitative stratigraphic correlation of lithounits and microfacies of Barakar succession in two widely separated borehole sections from Talchir coalfield, Orissa display strikingly different results. When major lithounits are considered, one-to-one correspondence between the two sections becomes significant and indicates the continuity of single homogeneous succession deposited under an identical depositional environment. Lack of significant correlation of microfacies, on the other hand, suggests existence of different subenvironments at different places during each phase of sedimentation. Thus a coal seam is likely to be restricted in its lateral continuity and show differences in the nature of floor and roof rocks, which are vital for safe and economic mining.

**Keywords:** Quantitative stratigraphic correlation, Barakar Formation, Depositional environment, Talchir coalfield, Orissa.

### INTRODUCTION

Stratigraphic correlation is the demonstration of equivalency of stratigraphic units (Krumbein and Sloss, 1963, p.332). Conventional stratigraphic correlation is generally based on litho-, bio- and chrono-stratigraphic criteria. Objective correlation, on the other hand, is of recent origin and based on cross-association analysis of lithounits/microfacies in stratigraphic columns. It involves standard statistical test and can be applied to correlate vertical succession of lithologies/microfacies. In India, this method has been applied to correlate vertical succession of microfacies in two carbonate sections, spatially more than 300 km apart, from the Sub-Himalaya of northwest India and their lateral continuity as well as similar depositional model has been established (Rao et al. 1985). The borehole sections of coal-bearing Gondwana sequence represent superposition of discrete lithologies like sandstone, shale and coal, which are further divisible into a number of microfacies on the basis of texture. The coal seams have long been used as marker horizons for lithostratigraphic correlation. However, this method seems inadequate to explain equivalency of inter-

seam microfacies, particularly in coal-bearing Barakar Formation. In view of this, experimental attempt has been made to correlate two vertical succession of lithologies and microfacies separately in two borehole sections of the Barakar Formation in Talchir coalfield, Orissa by cross-association analysis. The result may help in building a generalised sedimentation model useful in the exploration of Barakar coal in the basin.

The area under study is located in the south-eastern part of the Talchir coalfield (Fig.1) which is the southeastern end member of Son-Mahanadi basin. More than 300 boreholes have been drilled by different agencies like Indian Bureau of Mines (IBM), Central Mine Planning and Design Institute (CMPDI), Geological Survey of India (GSI) and Directorate of Mining and Geology (DMG), Govt. of Orissa for exploration of coal in the area. Two of these boreholes (Fig. 1) drilled and logged by CMPDI have been used in the present study.

### GEOLOGICAL SETTING

The Gondwana sediments of the present area represent a fairly continuous succession of strata
