One of the most fascinating recent developments in research has been how different disciplines have become more and more interconnected So much so that fields as disparate as information theory and fundamental physics have combined to produce ideas for the next generation of computing and secure information technologies both of which have far reaching consequences For more than fifty years Moore's law which describes the trend of the transistor's size shrinking by half every two years has proven to be uncannily accurate However the computing industry is now approaching a fundamental barrier as the size of a transistor approaches that of an individual atom and the laws of physics and quantum mechanics take over Rather than look at this as the end quantum information science has emerged to ask the question of what additional power and functionality might be realized by harnessing some of these quantum effects This thesis presents work on the sub field of quantum cryptography which seeks to use quantum means in order to assure the security of one's communications The beauty of quantum cryptographic methods are that they can be proven secure now and indefinitely into the future relying solely on the validity of the laws of physics for their proofs of security This is something which is impossible for nearly all current classical cryptographic methods to claim The thesis begins by examining the first implementation of an entangled quantum key distribution system over two free space optical links This system represents the first test bed of its kind in the world and while its practical importance in terrestrial applications is limited to a smaller university or corporate campus the system mimics the setup for an entangled satellite system aiding in the study of distributing entangled photons from an orbiting satellite to two earthbound receivers Having completed the construction of a second free space link and the automation of the alignment system I securely distribute keys

to Alice and Bob in two distant locations separated by 1 575 m with no direct line of sight between them I examine all of the assumptions necessary for my claims of security something which is particularly important for moving these systems out of the lab and into commercial industry I then go on to describe the free space channel over which the photons are sent and the implementation of each of the major system components I close with a discussion of the experiment which saw raw detected entangled photon rates of 565 s⁻¹ and a quantum bit error rate QBER of 4.92% resulting in a final secure key rate of 85 bits s⁻¹ Over the six hour night time experiment I was able to generate 1 612 239 bits of secure key With a successful QKD experiment completed this thesis then turns to the problem of improving the technology to make it more practical by increasing the key rate of the system and thus the speed at which it can securely encrypt information It does so in three different ways involving each of the major disciplines comprising the system measurement hardware source technology and software post processing First I experimentally investigate a theoretical proposal for biasing the measurement bases in the QKD system showing a 79% improvement in the secret key generated from the same raw key rates Next I construct a second generation entangled photon source with rates two orders of magnitude higher than the previous source using the idea of a Sagnac interferometer More importantly the new source has a QBER as low as 0.93% which is not only important for the security of the QKD system but will be required for the implementation of a new cryptographic primitive later Lastly I study the free space link transmission statistics and the use of a signal to noise ratio SNR filter to improve the key rate by 25.2% from the same amount of raw key The link statistics have particular relevance for a current project with the Canadian Space Agency to exchange a quantum key with an orbiting satellite a project which I have participated in two feasibility studies for Wanting to study the usefulness of more recent ideas in quantum cryptography this thesis then looks at the first experimental implementation of a new cryptographic primitive called oblivious transfer OT in the noisy storage model This primitive has obvious important applications as it can be used to implement a secure identification scheme provably secure in a quantum scenario Such a scheme could one day be used for example to authenticate a user over short distances such as at ATM machines which have proven to be particularly vulnerable to hacking and fraud Over a four hour experiment Alice and Bob measure 405 642 088 entangled photon pairs with an average QBER of 0.93% allowing them to create a secure OT key of 8 939 150 bits As a first implementer I examine many of the pressing issues currently preventing the scheme from being more widely adopted such as the need to relax the dependence of the OT rate on the loss of the system and the need to extend the security proof to cover a wider range of quantum communication channels and memories It is important to note that OT is fundamentally different than QKD for security as the information is never physically exchanged over the communication line but rather the joint equality function $f(x)f(y)$ is evaluated Thus security in QKD does not imply security for OT Finally this thesis concludes with the construction and initial alignment of a second generation free space quantum receiver useful for increasing the QKD key rates but designed for a fundamental test of quantum theory namely a Svetlichny inequality violation

Svetlichny's inequality is a generalization of Bell's inequality to three particles where any two of the three particles may be non locally correlated. Even so, a violation of Svetlichny's inequality shows that certain quantum mechanical states are incompatible with this restricted class of non local yet realistic theories. Svetlichny's inequality is particularly important because while there has been an overwhelming number of Bell experiments performed testing two body correlations, experiments on many body systems have been few and far between. Experiments of this type are particularly valuable to explore since we live in a many body world. The new receiver incorporates an active polarization analyzer capable of switching between measurement bases on a microsecond time scale through the use of a Pockels cell while maintaining measurements of a high fidelity. Some of the initial alignment and analysis results are detailed including the final measured contrasts of 1.25/2 and 1.22/6 in the rectilinear and diagonal bases respectively.

Cryptography Christian Kollmitzer, Mario Pivk, 2010-02-28 Using the quantum properties of single photons to exchange binary keys between two partners for subsequent encryption of secret data is an absolutely novel technology. Only a few years ago quantum cryptography or better Quantum Key Distribution was the domain of basic research laboratories at universities. But during the last few years things changed. Quantum Key Distribution or QKD left the laboratories and was picked up by more practical oriented teams that worked hard to develop a practically applicable technology out of the astonishing results of basic research. One major milestone toward a QKD technology was a large research and development project funded by the European Commission that aimed at combining quantum physics with complementary technologies that are necessary to create a technical solution. Electronics, software and network components were added within the project SECOQC. Development of a Global Network for Secure Communication based on Quantum Cryptography that teamed up all expertise on European level to get a technology for future cryptography.
