Computational Aspects of Linear Control Claude Brezinski, 2013-12-01 Many devices we say dynamical systems or simply systems behave like black boxes they receive an input this input is transformed following some laws usually a differential equation and an output is observed The problem is to regulate the input in order to control the output that is for obtaining a desired output Such a mechanism where the input is modified according to the output measured is called feedback The study and design of such automatic processes is called control theory As we will see the term system embraces any device and control theory has a wide variety of applications in the real world Control theory is an interdisciplinary domain at the junction of differential and difference equations system theory and statistics Moreover the solution of a control problem involves many topics of numerical analysis and leads to many interesting computational problems linear algebra QR SVD projections Schur complement structured matrices localization of eigenvalues computation of the rank Jordan normal form Sylvester and other equations systems of linear equations regularization etc root localization for polynomials inversion of the Laplace transform computation of the matrix exponential approximation theory orthogonal polynomials Padé approximation continued fractions and linear fractional transformations optimization least squares dynamic programming etc So control theory is also a good excuse for presenting various sometimes unrelated issues of numerical analysis and the procedures for their solution This book is not a book on control

Numerical Methods for Large-Scale Linear Time-Varying Control Systems and related Differential Matrix Equations Norman Lang, 2018 This thesis is concerned with the linear quadratic optimal control and

model order reduction MOR of large scale linear time varying LTV control systems In the first two parts particular attention is paid to a tracking type finite time optimal control problem with application to an inverse heat conduction problem and the balanced truncation BT MOR method for LTV systems In both fields of application the efficient solution of differential matrix equations DMEs is of major importance The third and largest part deals with the application of implicit time integration methods to these matrix valued ordinary differential equations In this context in particular the rather new class of peer methods is introduced Further for the efficient solution of large scale DMEs in practice low rank solution strategies are inevitable Here low rank time integrators based on a symmetric indefinite factored representation of the right hand sides and the solution approximations of the DMEs are presented In contrast to the classical low rank Cholesky type factorization this avoids complex arithmetic and tricky implementations and algorithms Both low rank approaches are compared for numerous implicit time integration methods
