ABSTRACT – Instrumented indentation technique gives the possibility to determine the mechanical properties for small specimens and material in service. Several researchers have attempted to evaluate this approach experimentally and investigated the factors that affect it by using different indenter geometries for different engineering materials. In this work, the instrumented indentation technique was used to evaluate the mechanical properties experimentally and numerically using finite element simulation to understand the contact mechanics between the indenter surface and the substrate for two types of steel alloys namely ASTM A16-G70 and AISI 1010 steel. Two shapes of indenters, blunt (spherical) and sharp (Vickers) were used. The results were then compared with the experimental results extracted from the instrumented indentation test. The results have demonstrated a good agreement between the experimental and the finite element simulation results with error bound a $\pm 5\%$ for young's modulus and $\pm 7.7\%$ for yield strength. Whereas excellent agreement is observed in the elastic region and the beginning of the plastic region for the true stress-strain curve. Finally, it is to be emphasized that the obtained results are more applicable for the tested materials and further research is recommended to accommodate other materials as well and to confirm the generality of this method.

INTRODUCTION

An instrumented indentation test or sometimes called depth-sensing indentation instrument used to obtain mechanical properties such as hardness, Young's modulus, and yield strength by analyzing the load-displacement curve. The instrumented indentation test can be performed on a macro or nano-scale using a variety of indenters geometries and the load-displacement curve will represent the shape of the indenter. In microscale, indentation the hardness test was widely used to determine the effect of surface processing such as hardening or coating for different materials, due to the difficulty of performing another mechanical testing [1]. Instrumented indentation test is relatively new and still under development to be more flexible and trust-worthy in use in the field applications. The elastic-plastic response of materials during the indentation has been extensively investigated in the literature experimentally and theoretically [2-6,20]. Determination of the exact shape of the indenter at the tip is important to measure the mechanical properties such as the hardness and the elastic modulus for indentation depths less than a micro-scale [7].

The finite element method has been used to simulate the conical indentation hardness test of elastoplastic micropolar material by S. Hassan Sakhi *et al.* [8] Indentation load-depth curves were obtained, and the elastic modulus was calculated. Results justified and showed that the shapes of the plastic zones depend strongly on both the indenter angle and the ratio of young's modulus to yield strength. Where the yield zone of Aluminum ($E/\sigma_y = 157.1$) is bigger than the yield zone of silicon ($E/\sigma_y = 28.8$) [8].

Because of the non-linear nature of the indentation hardness test (elasto-plastic behaviour), it is quite hard to obtain the mechanical properties directly from the experimental load-displacement curve. J. A. Knapp *et al.* [9] attempted to characterize layers and thin films using finite element modelling. The yield strength, Young's modulus, and hardness of the layer material extracted, with an absolute accuracy of at least 20% [9]. Improving the test equipment for instrumented indentation method and consideration to the error sources such as the error due to pile-up or sinking in is a way to make it more accurate. Test procedures and concepts are still demanding to improve the method that was introduced 10 years ago [10]. Recently, a good agreement between experimental Nanoindentation hardness test for bulk material and finite element simulation in a two-dimensional (2-D) axisymmetric model and a three-dimensional (3-D) model have been obtained by using finite element analysis [11]. Numerical simulations of pure copper, pure titanium, pure iron, and copper film were obtained using FE simulation. It is found that the result depended greatly on mesh size, indenter radius, and the hardening model used to simulate the indentation test [12]. Also, a finite element model for spherical indentation test for metallic substrates have been developed and the results were found to be relatively in close agreement to experimental data with a very minor effect of Poisson's ratio on the load-displacement curve; however, the polymeric materials was less successful because of the effects of anisotropy strain rate dependence e.g., a viscosity [13]. Continuous instrumented indentation test with the Oliver-Pharr method using Vickers's indenter under load values from (10 to 100 N) was
