### Abstract

Functional block diagrams (FBDs) and their equivalent event trees are introduced as logical models in the quantification of occupational risks. Although a FBD is similar to an influence diagram or a belief network it provides a framework for introduction in a compact form of the logic of the model through the partition of the paths of the equivalent event tree. This is achieved by consideration of an overall event which has as outcomes the outmost consequences defining the risk under analysis. This event is decomposed into simpler events the outcome space of which is partitioned into subsets corresponding to the outcomes of the initial joint event. The simpler events can be further decomposed into simpler events creating a hierarchy where the events in a given level (parents) are decomposed to a number of simpler events (children) in the next level of the hierarchy. The partitioning of the outcome space is transferred from level to level through logical relationships corresponding to the logic of the model.

Occupational risk is modeled through a general FBD where the undesirable health consequence is decomposed to “dose” and “dose/response”; “dose” is decomposed to “center event” and “mitigation”; “center event” is decomposed to “initiating event” and “prevention”. This generic FBD can be transformed to activity—specific FBDs which together with their equivalent event trees are used to delineate the various accident sequences that might lead to injury or death consequences.

The methodology and the associated algorithms have been computerized in a program with a graphical user interface (GUI) which allows the user to input the functional relationships between parent and children events, corresponding probabilities for events of the lowest level and obtain at the end the quantified corresponding simplified event tree.

The methodology is demonstrated with an application to the risk of falling from a mobile ladder. This type of accidents has been analyzed as part of the Workgroup Occupational Risk Model (WORM) project in the Netherlands aiming at the development and quantification of models for a full range of potential risks from accidents in the workplace.

### 1. Introduction

Occupational safety and health is the ongoing concern for the ministry of Social Affairs and Employment in the Netherlands. Many programs have been developed over the years to reduce the number of accidents. Although the reduction of human suffering associated with occupational

accidents is the prime reason for these concerns, the material damage in the form of sick leave, reduced family income and medical care also drives the Dutch government to seek reduction of occupational risk. Whereas the occupational policies up to now were based on qualitative insight existing in industry and in the public services, for the future the Dutch government is seeking an approach based on the experience with the policy on external safety, or third party risk [1–5]. This policy is based on quantitative analysis of risk, on determination of the dominant paths to accidents from accident statistics and reducing risks by targeting the dominant threats first. This
