Abstract. An integral computer model/program AusEvol Pro was developed to describe the evolution of steel microstructure during thermomechanical processing (hot rolling, forging), as well as subsequent heat treatment (normalization, tempering), and to evaluate the final mechanical properties (yield stress, tensile stress, elongation), hardness and impact toughness. The program implements a set of physically based models that allow quantitative description of all significant processes of steel structure formation with account of the effects of chemical composition both during thermomechanical processing and heat treatment. Calculations of the final mechanical properties are carried out using the developed models that take into account all physically meaningful contributions. The models created are verified both on the extensive database of our own experimental studies and on reliable data from literature for steels of various chemical compositions.

Keywords: heat treatment, mechanical property, microstructure, modeling, steel, thermo-mechanical processing

1. Introduction

In the last 30 years considerable attention has been paid to the development of integral quantitative models which enable describing a complex evolution of the microstructure of steels under their thermomechanical processing in industrial hot rolling and subsequent accelerated cooling, as well as predicting the final mechanical properties [1-7]. Such integral models, implemented with computer programs [6,7], are successfully used in the practice of industrial production, allowing to optimize the rolling modes of existing steel grades, as well as to quickly develop new steel grades and their production modes. However, the microstructure of thermomechanically processed steels evolves further during additional heat treatments (normalization or tempering); thus, to develop the physically based models for underlying processes is a task of great practical significance which currently receives considerable attention.

This paper briefly describes the integral computer model/program AusEvol Pro that was developed to predict the evolution of steel microstructure during both the thermomechanical processing and subsequent heat treatment, as well as to evaluate the final mechanical properties (yield stress, tensile stress, elongation), hardness and impact toughness. The resulting final properties of steels after the hot rolling and the latter in combination with subsequent heat treatment, performed in accordance with real industrial conditions, are compared with experimental data.

Microstructures play an important role in controlling distribution of properties in engineering materials It is possible to develop components with tailored distribution of properties such as strength and stiffness by controlling microstructure evolution during the manufacturing process When forming metallic components by imposing large deformations mechanisms such as slip and lattice rotation drive formation of texture in the underlying polycrystalline microstructure Such microstructural changes affect the final distribution of material properties in the component By carefully designing the imposed deformation one could potentially tailor the microstructure and obtain desired property distributions This thesis focuses on development of novel computational strategies for designing deformation processes to realize materials with desired properties The techniques presented are an interplay of several new tools developed recently such as reduced order modeling graphical cross plots statistical learning microstructure homogenization and multi scale sensitivity analysis The primary outcomes of this thesis are listed below Development of reduced order representations and graphical methodologies for representing process property texture relationships Development of adaptive reduced order optimization techniques for identification of processing paths that lead to desirable microstructure sensitive properties Development of homogenization techniques for predicting microstructure evolution in large deformation processes Development of multi scale sensitivity analysis of poly crystalline material deformation for optimizing microstructure sensitive properties during industrial forming processes The framework for design of polycrystalline microstructures leads to increased product yield in industrial forming processes and simultaneously allows control distribution of properties such as stiffness and strength in forged products Multiscale design problems leading to billions of unknowns have been solved using parallel computing techniques The computational framework can be readily used for selecting optimal processing paths for achieving desired properties The methodology developed is a fundamental effort at providing detailed deformation process design solutions needed for controlling properties of performance critical hardware components in automotive structural and aerospace applications
