

Sliding Mode Neurocontrol with Applications

Alexander Poznyak, Isaac Chairez⁽¹⁾, Tatyana Poznyak⁽²⁾

Abstract—In this study the tracking problem for a class of nonlinear uncertain systems is tackled. A new sliding mode neurocontroller is suggested to solve this problem. The designing of this controller includes the construction of on-line state estimates and the corresponding tracking control based on sliding mode approach using obtained state estimates. We apply a special sliding mode technique during the “off-line training” to estimate the right-hand side of the given dynamics in finite-time and then to use these estimates for the best (in LQ-sense) nominal weights selection in the designed neuro observer. A switching (sign) type term is incorporated in to the observer structure to correct the current state estimates using only available and on-line measurable output data supplied with a new learning procedure with a relay term. The illustrative example dealing with a real water sanitation process is presented.

I. INTRODUCTION

Over the past decades, considerable research efforts had been undertaken on control design for uncertain nonlinear dynamic systems. Uncertainties in dynamic systems, commonly occurred in actual applications, provoke considerable troubles in any control realization being a source of instability or poor performance. Several approaches are known to synthesize a control in this situation. Two most effective of them, as it is widely recognized, are the Neural Network Approach and the Sliding Mode technique. Practically, there are few publications considering the application of both of them simultaneously [13], [10]. Such combinations of basic ideas of both methods seems to be very promising providing a new instrument for identification and control of a wide class of systems with uncertainties. This paper presents the realization of this idea and suggests the control design based on both *Dynamic Neural Network Observation* and *Sliding Mode Technique*, applied to the obtained neural network model. Below this approach is referred to as *Sliding Mode Neurocontrol*.

Research on *adaptive output feedback control of uncertain nonlinear dynamic systems* is of paramount importance today, particularly considering the growing interest in the use of unconventional control devices such as chemical sensors, piezoelectric actuators, etc. In a large number of practical problems there are important disturbances, uncertainties or several parameter variations. In these situations a solution of the control problem is given by the, so-called, unconventional adaptive control supplied by a mechanism for

adjusting the parameters of controllers [1]. A solution of the output feedback stabilization problem for systems in which nonlinearities depend only upon the available measurement, is given in [14]. In [8], backstepping -based approach is used and its extension is in [6], [7] and [17].

There exists another effective approach to identify and control a wide class of unknown systems: it is *Sliding Mode Control* (SMC) [18] which applies the relay (discontinuous) feedback to reach and maintain the closed-loop dynamics on a certain manifold (in the state space) with a corresponding desired properties. This control offers significant potential advantages comparing to other identification and control techniques: good transient behavior, global exponential stability of a small estimation error, no modeled disturbance rejection capability, insensitivity to plant nonlinearities or parameter variations and remarkable stability and performance robustness [16], [18]. In this study we suggest a dynamic neuro observer (see the subsection below), which incorporates switching type term to correct current state estimates using only available measurable output data.

Artificial Neural Networks (NN) have shown good identification properties in the presence of some uncertainties or external disturbances. There are known two type of NN: *static* one, using the, so-called, back-propagation technique [5] and *dynamic* neural networks (DNN), [15]. The first one deal with the class of global optimization problems trying to adjust the weights of such NN to minimize an identification error. The second approach, exploiting the feedback properties of the applied DNN, permits to avoid many problems related to global extremum search converting the learning process to an adequate feedback design, [10], [9]. Several approaches dealing with state estimation problem are widely used in practical applications. Among them there are the Lie-algebraic method [7], Lyapunov-like observers [16], high gain observation [4], the reduced-order nonlinear observers [3] and others. Dynamic neuro-observers are studied in [10], [12] and [13].

A. Motivation

One of the most attractive feature of the SMC approach is its finite-time convergence for controlled trajectories to a desired sliding surface [18]. The realization of such control demands the complete knowledge of all current states of the system to be controlled. Obviously when dealing with SMC and only output (no state) information is available for a designer, it turns out to be useless when it's applied directly. Thus SMC application demands state observer designing to keep all its attractive features. When a nonlinear model of a controlled system is a priori unknown exactly, the state
